Entecavir in Hepatitis B Virus (HBV)/HIV Co-Infected Patients

Previously, the guidelines recommended entecavir as an option for patients who required treatment for Hepatitis B virus (HBV) but not HIV infection. This recommendation was based on in vitro data showing no significant activity of entecavir against HIV-1 [1]. A recent case series of three patients who received entecavir without concomitant antiretroviral therapy reported a 1 log\(_{10}\) decline in HIV-RNA levels and emergence of M184V mutations in one patient who was studied in detail [2].

Based on these preliminary findings, the Panel recommends that:

For HBV/HIV co-infected patients, entecavir should not be used for the treatment of HBV infection without concomitant treatment for HIV.
